
Ghini Documentation

Release 1.0.50

Brett Adams

giugno 23, 2017

Indice

1	Statements	3
2	Istallare Bauble	11
3	Uso di Ghini	21
4	Amministrazione	41
5	Sviluppo di Ghini	43
6	Appoggiare Ghini	55

Ghini è un programma per la gestione di collezioni di oggetti botanici. Con Ghini puoi creare una base dati di registri di piante, con molte opzioni di ricerca.

Ghini è software [aperto](#) e [libero](#) ed è distribuito secondo la [GPL: Licenza Pubblica GNU](#)

Ghini's goals and highlights

Should you use this software? This question is for you to answer. We trust that if you manage a botanic collection, you will find Ghini overly useful and we hope that this page will convince you about it.

This page shows how Ghini makes software meet the needs of a botanic garden.

Botanic Garden

According to the Wikipedia, »A botanic(al) garden is a garden dedicated to the collection, cultivation and display of a wide range of plants labelled with their botanical names«, and still according to the Wikipedia, »a garden is a planned space, usually outdoors, set aside for the display, cultivation, and enjoyment of plants and other forms of nature.«

So we have in a botanic garden both the physical space, the garden, as its dynamic, the activities to which the garden is dedicated, activities which makes us call the garden a botanic garden.

Botanic Garden Software

At the other end of our reasoning we have the application program Ghini, and again quoting the Wikipedia, »an application program is a computer program designed to perform a group of coordinated functions, tasks, or activities for the benefit of the user«, or, in short, »designed to help people perform an activity«.

Data and algorithms within Ghini have been designed to represent the physical space and the dynamic of a botanic garden.

Fig. 1.1: the physical garden

Fig. 1.2: collection related activities in the garden

Fig. 1.3: core structure of Ghini's database

The central element in Ghini's point of view is the `Accession`. Following its links to other database objects lets us better understand the structure:

An `Accession` represents the action of receiving plant material in the garden. As such, `Accession` is an abstract concept, it links physical living `Plantings`—groups of plants placed each at a `Location` in the garden—to the corresponding `Species`. An `Accession` has zero or more `Plantings` associated to it (0..n), and it is at all times connected to exactly 1 `Species`. Each `Planting` belongs to exactly one `Accession`, each `Species` may have multiple `Accessions` relating to it.

An `Accession` stays in the database even if all of its `Plantings` have been removed, sold, or have died. Identifying the `Species` of an `Accession` consistently connects all its `Plantings` to the `Species`.

`Propagations` and `Contacts` provide plant material for the garden; this information is optional and smaller collectors might prefer to leave this aside. A `Propagation` trial may be unsuccessful, most of the time it will result in exactly one accession, but it may also produce slightly different taxa, so the database allows for zero or more `Accessions` per `Propagation` (0..n). Also a `Contact` may provide zero or more `Accessions` (0..n).

Specialists may formulate their opinion about the `Species` to which an `Accession` belongs, by providing a `Verification`, signing it, and stating the applicable level of confidence.

If an `Accession` was obtained in the garden nursery from a successful `Propagation`, the `Propagation` links the `Accession` and all of its `Plantings` to a single parent `Planting`, the seed or the vegetative parent.

Even after the above explanation, new users generally still ask why they need pass through an `Accession` screen while all they want is to insert a `Plant` in the collection, and again: what is this “accession” thing anyway? Most discussions on the net don't make the concept any clearer. One of our users gave an example which I'm glad to include in Ghini's documentation.

use case

1. At the beginning of 2007 we got five seedlings of *Heliconia longa* (a plant `Species`) from our neighbour (the `Contact` source). Since it was the first acquisition of the year, we named them 2007.0001 (we gave them a single unique `Accession` code, with quantity 5) and we planted them all together at one `Location` as a single `Planting`, also with quantity 5.
2. At the time of writing, nine years later, `Accession` 2007.0001 has 6 distinct `Plantings`, each at a different `Locations` in our garden, obtained vegetatively (asexually) from the original 5 plants. Our only intervention was splitting, moving, and of course writing this information in the database. Total plant quantity is above 40.
3. New `Plantings` obtained by (assisted) sexual `Propagation` come in our database under different `Accession` codes, where our garden is

the `Contact` source and where we know which of our `Plantings` is the seed parent.

the above three cases translate into several short usage stories:

1. activate the menu `Insert` → `Accession`, verify the existence and correctness of the Species *Heliconia longa*, specify the initial quantity of the `Accession`; add its `Planting` at the desired `Location`.
2. edit `Planting` to correct the amount of living plants — repeat this as often as necessary.
3. edit `Planting` to split it at separate `Locations` — this produces a different `Planting` under the same `Accession`.
4. edit `Planting` to add a (seed) `Propagation`.
5. edit `Planting` to update the status of the `Propagation`.
6. activate the menu `Insert` → `Accession` to associate an accession to a successful `Propagation` trial; add the `Planting` at the desired `Location`.

In particular the ability to split a `Planting` at several different `Locations` and to keep all uniformly associated to one `Species`, or the possibility to keep information about `Plantings` that have been removed from the collection, help justify the presence of the `Accession` abstraction level.

Our User Stories section contains details about the above, and more.

Highlights

not-so-brief list of highlights, meant to whet your appetite.

taxonomic information

When you first start Ghini, and connect to a database, Ghini will initialize the database not only with all tables it needs to run, but it will also populate the taxon tables for ranks family and genus, using the data from the “RBG Kew’s Family and Genera list from Vascular Plant Families and Genera compiled by R. K. Brummitt and published by the Royal Botanic Gardens, Kew in 1992”. In 2015 we have reviewed the data regarding the Orchidaceae, using “Tropicos, botanical information system at the Missouri Botanical Garden - www.tropicos.org” as a source.

importing data

Ghini will let you import any data you put in an intermediate json format. What you import will complete what you already have in the database. If you need help, you can ask some Ghini professional to help you transform your data into Ghini’s intermediate json format.

synonyms

Ghini will allow you define synonyms for species, genera, families. Also this information can be represented in its intermediate json format and be imported in an existing Ghini database.

scientific responsible

Ghini implements the concept of ‘accession’, intermediate between physical plant (or a group thereof) and abstract taxon. Each accession can associate the same plants to different taxa, if two taxonomists do not agree on the identification: each taxonomist can have their say and do not need overwrite each other’s work. All verifications can be found back in the database, with timestamp and signature.

helps off-line identification

Ghini allows you associate pictures to physical plants, this can help recognize the plant in case a sticker is lost, or help taxonomic identification if a taxonomist is not available at all times.

exports and reports

Ghini will let you export a report in whatever textual format you need. It uses a powerful templating engine named ‘mako’, which will allow you export the data in a selection to whatever format you need. Once installed, a couple of examples are available in the mako subdirectory.

annotate your info

You can associate notes to plants, accessions, species, Notes can be categorized and used in searches or reports.

garden or herbarium

Management of plant locations.

database history

All changes in the database is stored in the database, as history log. All changes are ‘signed’ and time-stamped. Ghini makes it easy to retrieve the list of all changes in the last working day or week, or in any specific period in the past.

simple and powerful search

Ghini allows you search the database using simple keywords, e.g.: the name of the location or a genus name, or you can write more complex queries, which do not reach the complexity of SQL but allow you a decent level of detail localizing your data.

database agnostic

Ghini is not a database management system, so it does not reinvent the wheel. It works storing its data in a SQL database, and it will connect to any database management system which accepts a SQLAlchemy connector. This means any reasonably modern database system and includes MySQL, PostgreSQL, Oracle. It can also work with sqlite, which, for single user purposes is quite sufficient and efficient. If you connect Ghini to a real database system, you can consider making the database part of a LAMP system (Linux-Apache-MySQL-Php) and include your live data on your institution web site.

language agnostic

The program was born in English and all its technical and user documentation is still only in that language, but the program itself has been translated and can be used in various other languages, including Spanish (86%), Portuguese (100%), French (42%), to name some Southern American languages, as well as Swedish (100%) and Czech (100%).

platform agnostic

Installing Ghini on Windows is an easy and linear process, it will not take longer than 10 minutes. Ghini was born on Linux and installing it on ubuntu, fedora or debian is consequently even easier. MacOSX being based on unix, it is possible to successfully run the Linux installation procedure on any recent Apple computer, after a few preparation steps.

easily updated

The installation process will produce an updatable installation, where updating it will take less than one minute. Depending on the amount of feedback we receive, we will produce updates every few days or once in a while.

unit tested

Ghini is continuously and extensively unit tested, something that makes regression of functionality close to impossible. Every update is automatically quality checked, on the Travis Continuous Integration service. Integration of TravisCI with the github platform will make it difficult for us to release anything which has a single failing unit test.

Most changes and additions we make, come with some extra unit test, which defines the behaviour and will make any undesired change easily visible.

customizable/extensible

Ghini is extensible through plugins and can be customized to suit the needs of the institution.

Mission & Vision

Here we state who we are, what we think of our work, what you can expect of this project.

Who is behind Ghini

Ghini started as a one-man project, by Brett Adams. He started this software as Bauble, for and at the Belize Botanical Garden, and later on adapted it to the needs of a couple of other users who asked him. Brett made Bauble a commons, by releasing it under a GPL license.

After some years of stagnation Mario Frasca took responsibility of updating Bauble, rebranded it to Ghini, in honour of Luca Ghini, started adocating, travelling, distributing, developing, documenting it, and it is now Mario Frasca writing this, enhancing the software, looking for users, requesting feedback...

So currently behind Ghini there's not only one developer, but much more importantly, a small but growing global users community.

Translations are provided by volunteers who mostly stay behind the scenes, translating a couple of missing terms or sentences, and disappearing again.

To make things clearer when we speak of Ghini, but should—and in this document we will—indicate whether it's Ghini(the software), or Ghini(the people), unless obviously we mean both things.

Mission

The Mission Statement is a purpose, it defines the rationale of an entity and is specific and true. For Ghini, the Mission Statement sets out the social order to which Ghini is committed, the needs that are satisfied with Ghini(the software) and with the services of Ghini(the people), the market in which Ghini develops and its intended public image.

- access to software
- access to development
- bundling resources
- open source
- open data
- community forming

Vision

The Vision serves to indicate the way ahead and projects a future image of what we want our organization to be, in a realistic and attractive way. It serves as motivation because it visualizes the challenge and direction of necessary changes in order to grow and prosper.

- by the year 2020
- reference point
- community
- development
- integration with web portal
- geographic information

CAPITOLO 2

Installare Bauble

Installazione

ghini.desktop è un programma multiplatforma e funziona su macchine unix (Linux e MacOSX) ma anche su Windows.

Per installare Ghini, c'è bisogno di soddisfare un paio di dipendenze che non possono essere risolte automaticamente. Queste includono virtualenvwrapper, PyGTK e pip. Python è presente su ogni macchina unix, mentre GTK+ è nativo di Linux ed altrimenti va installato. Dopo aver soddisfatte queste richieste, è possibile lasciare a Ghini il compito di risolvere tutte le altre.

Nota: Seguendo le seguenti istruzioni di installazione si ottiene un Ghini installato in un ambiente Python virtuale, tutte le dipendenze saranno installate localmente e non entreranno in conflitto con altri programmi Python che possono essere sullo stesso elaborator.

se dovessi in seguito decidere di rimuovere Ghini, basterà rimuovere l'ambiente virtuale, che è una directory, con tutto il suo contenuto.

Installare su Linux

Open a shell terminal window, and follow these instructions.

technical note

You can study the script to see what steps it runs for you. In short it will install dependencies which can't be satisfied in a virtual environment, then it will create a virtual envi-

environment named `ghide`, use `git` to download the sources to a directory named `~/Local/github/Ghini/ghini.desktop`, and connect this `git` checkout to the `ghini-1.0` branch (this you can consider a production line), it then builds `ghini`, downloading all remaining dependencies in the virtual environment, and finally it creates a startup script. If you have `sudo` permissions, it will be placed in `/usr/local/bin`, otherwise in your `~/bin` folder. Again if you

beginner's note

To run a script, first make sure you note down the name of the directory to which you have downloaded the script, then you open a terminal window and in that window you type `bash` followed by a space and the complete name of the script including directory name, and hit on the enter key.

1. Scaricare il programmino `devinstall.sh` ed eseguirlo:

```
https://raw.githubusercontent.com/Ghini/ghini.desktop/master/  
→scripts/devinstall.sh
```

Please note that the script will not help you install any extra database connector. This is not strictly necessary and you can do it at any later step.

Se il programmino di installazione termina senza errori, si può ora avviare `ghini`:

```
~/bin/ghini
```

o aggiornare `ghini` all'ultima versione rilasciata nella linea di produzione:

```
~/bin/ghini -u
```

The same script you can use to switch to a different production line. At the moment it's just `ghini-1.0` and `ghini-1.1`.

2. su Unity, apri un terminale, avvia `ghini`, la sua icona (il signor Ghini mostrando il suo erbario) apparirà nel *launcher*, e se si vuole lo si può saldare al launcher.
3. If you would like to use the default **SQLite** database or you don't know what this means then you can skip this step. If you would like to use a database backend other than the default SQLite backend then you will also need to install a database connector.

If you would like to use a **PostgreSQL** database then activate the virtual environment and install `psycopg2` with the following commands:

```
source ~/.virtualenvs/ghide/bin/activate  
pip install -U psycopg2
```

You might need solve dependencies. How to do so, depends on which GNU/Linux flavour you are using. Check with your distribution documentation.

Next...

Connecting to a database.

Installing on MacOSX

Being MacOSX a unix environment, most things will work the same as on GNU/Linux (sort of).

Last time we tested, some of the dependencies could not be installed on MacOSX 10.5 and we assume similar problems would also show on older OSX versions. Ghini has been successfully tested with 10.7, 10.9 and 10.12.

First of all, you need things which are an integral part of a unix environment, but which are missing in a off-the-shelf mac:

1. developers tools: xcode. check the wikipedia page for the version supported on your mac.
2. package manager: homebrew (tigerbrew for older OSX versions).

with the above installed, open a terminal window and run:

```
brew doctor
```

make sure you understand the problems it reports, and correct them. pygtk will need xquartz and brew will not solve the dependency automatically. either install xquartz using brew or the way you prefer:

```
brew install Caskroom/cask/xquartz
```

then install the remaining dependencies:

```
brew install git
brew install pygtk # takes time and installs all dependencies
```

follow all instructions on how to activate what you have installed.

Mac running OSX 10.12 —Sierra—

On OSX 10.12, brew reports that `gettext` is already installed, but then it won't let us find it. A solution is to run the following line:

```
brew link gettext --force
```

Before we can run `devinstall.sh` as on GNU/Linux, we still need installing a couple of python packages, globally. Do this:

```
sudo pip install virtualenv lxml
```

The rest is just as on a normal unix machine. Read the above GNU/Linux instructions, follow them, enjoy.

Next...

Connecting to a database.

Installing on Windows

The current maintainer of ghini.desktop has no interest in learning how to produce Windows installers, so the Windows installation is here reduced to the same installation procedure as on Unix (GNU/Linux and MacOSX).

Please report any trouble. Help with packaging will be very welcome, in particular by other Windows users.

The steps described here instruct you on how to install Git, Gtk, Python, and the python database connectors. With this environment correctly set up, the Ghini installation procedure runs as on GNU/Linux. The concluding steps are again Windows specific.

Nota: Ghini has been tested with and is known to work on W-XP, W-7 and W-8. Although it should work fine on other versions Windows it has not been thoroughly tested.

Nota: Direct download links are given for all needed components. They have been tested in September 2015, but things change with time. If any of the direct download links stops working, please ring the bell, so we can update the information here.

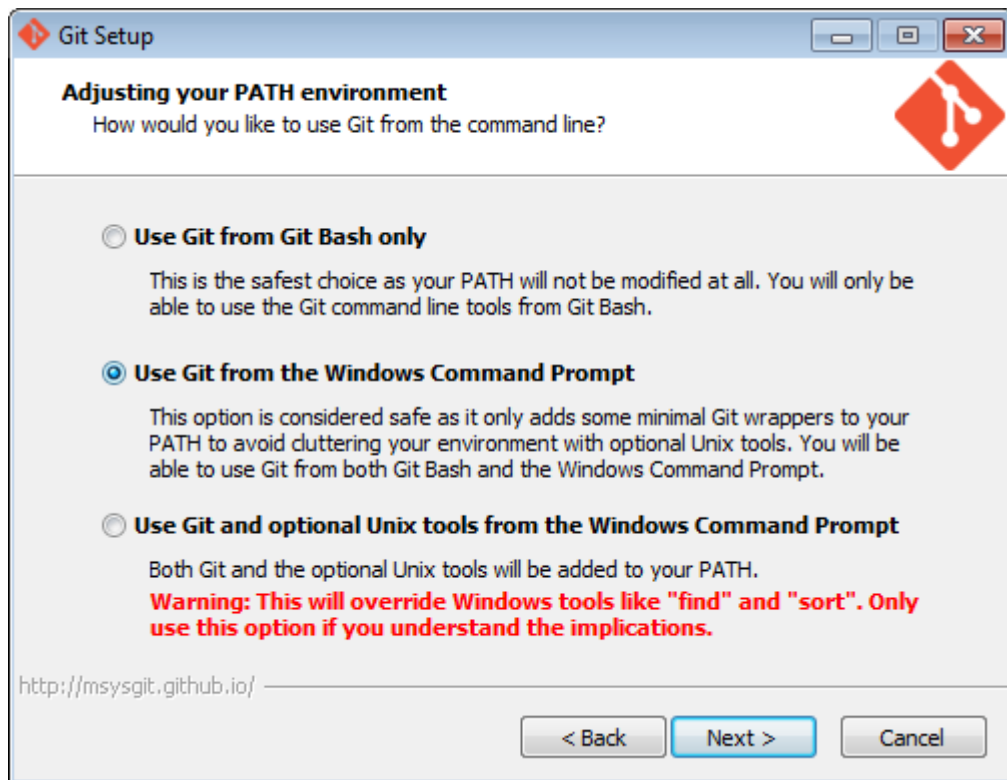

The installation steps on Windows:

1. download and install `git` (comes with a unix-like `sh` and includes `vi`) from:

<https://git-scm.com/download/win>

[Direct link to download git](#)

all default options are fine, except we need `git` to be executable from the command prompt:

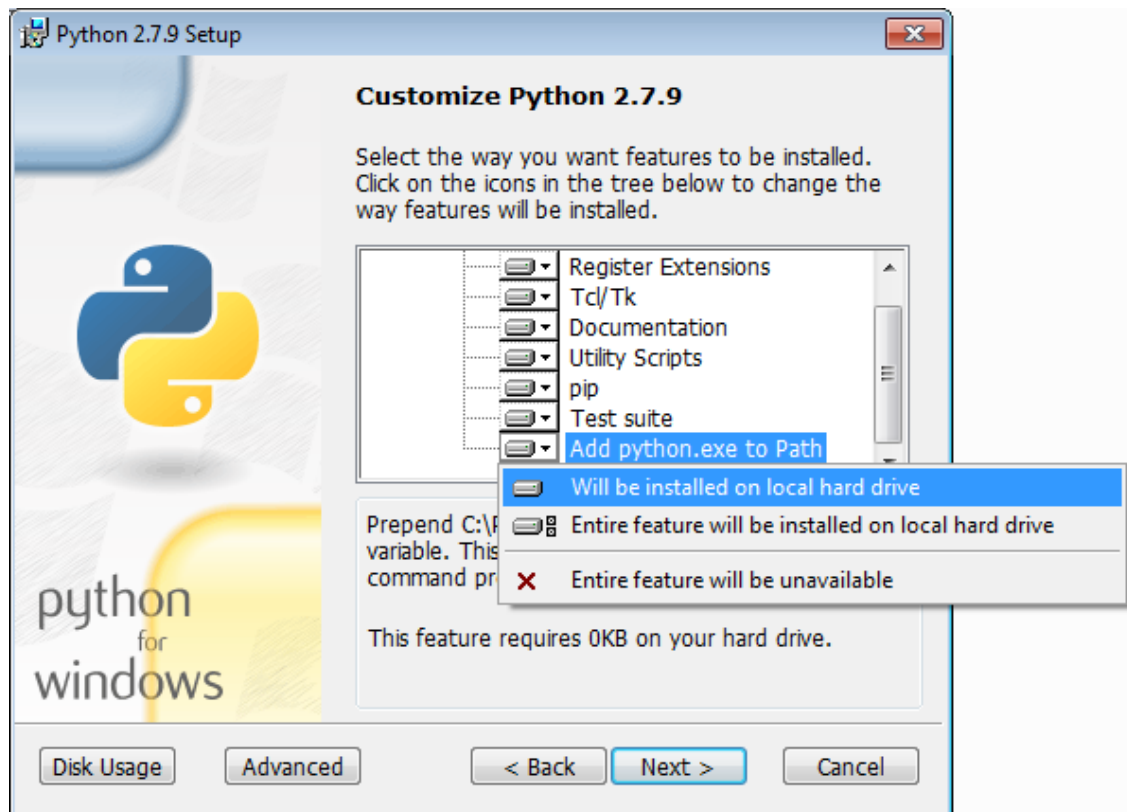

2. download and install Python 2.x (32bit) from:

<http://www.python.org>

[Direct link to download Python](#)

Ghini has been developed and tested using Python 2.x. It will definitely **not** run on Python 3.x. If you are interested in helping port to Python 3.x, please contact the Ghini maintainers.

when installing Python, do put Python in the PATH:

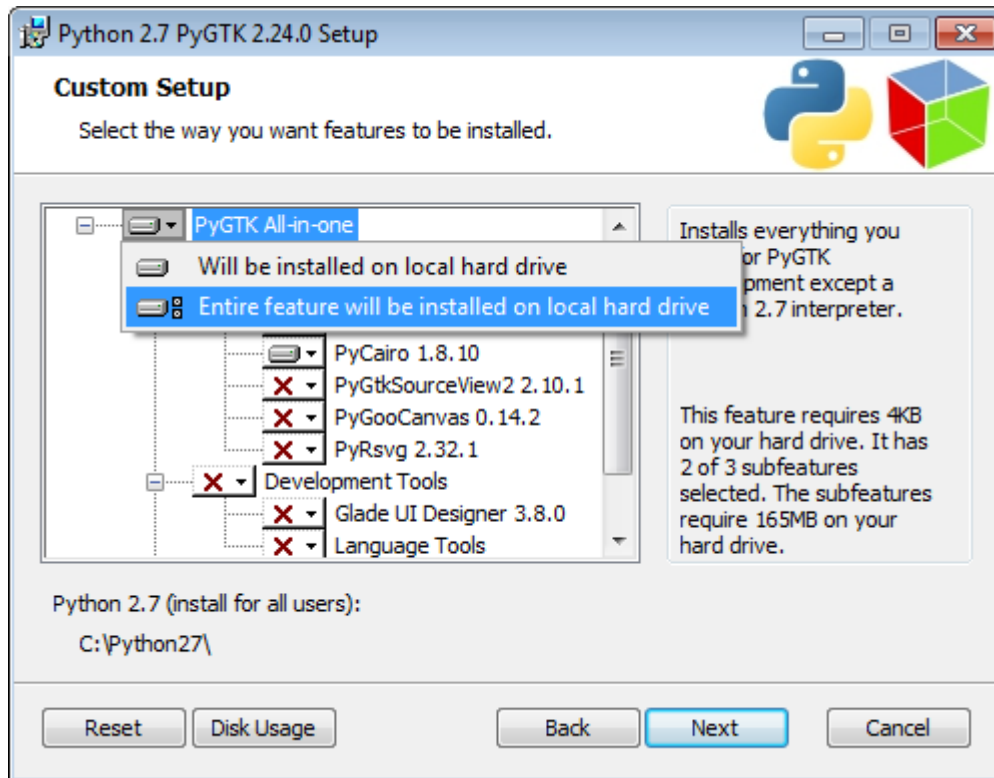

3. download `pygtk` from the following source. (this requires 32bit python). be sure you download the “all in one” version:

<http://ftp.gnome.org/pub/GNOME/binaries/win32/pygtk/>

Direct link to download PyGTK

make a complete install, selecting everything:

4. (Windows 8.x) please consider this additional step. It is possibly necessary to avoid the following error on Windows 8.1 installations:

```
Building without Cython.
ERROR: 'xslt-config' is not recognized as an internal or
external command,
operable program or batch file.
```

If you skip this step and can confirm you get the error, please inform us.

You can download lxml from:

```
https://pypi.python.org/pypi/lxml/3.4.4
```

Remember you need the 32 bit version, for Python 2.7.

[Direct link to download lxml](#)

5. (optional) download and install a database connector other than `sqlite3`.

On Windows, it is NOT easy to install `psycopg2` from sources, using `pip`, so “avoid the gory details” and use a pre-compiled package from:

<http://initd.org/psycopg/docs/install.html>

[Direct link to download psycopg2](#)

6. **REBOOT**

hey, this is Windows, you need to reboot for changes to take effect!

7. download and run (from `\system32\cmd.exe`) the batch file:

<https://raw.githubusercontent.com/Ghini/ghini.desktop/master/scripts/devinstall.bat>

right before you hit the enter key to run the script, your screen might look like something like this:

this will pull the `ghini.desktop` repository on github to your home directory, under `Local\github\Ghini`, checkout the `ghini-1.0` production line, create a virtual environment and install ghini into it.

you can also run `devinstall.bat` passing it as argument the numerical part of the production line you want to follow.

this is the last installation step that depends, heavily, on a working internet connection.

the operation can take several minutes to complete, depending on the speed of your internet connection.

8. the last installation step creates the Ghini group and shortcuts in the Windows Start Menu, for all users. To do so, you need run a script with administrative rights. The script is called `devinstall-finalize.bat`, it is right in your HOME folder, and has been created at the previous step.

right-click on it, select run as administrator, confirm you want it to make changes to your computer. These changes are in the Start Menu only: create the Ghini group, place the Ghini shortcut.

9. download the batch file you will use to stay up-to-date with the production line you chose to follow:

<https://raw.githubusercontent.com/Ghini/ghini.desktop/master/scripts/ghini-update.bat>

if you are on a recent Ghini installation, each time you start the program, Ghini will check on the development site and alert you of any newer ghini release within your chosen production line.

any time you want to update your installation, just start the command prompt and run `ghini-update.bat`

If you would like to generate and print PDF reports using Ghini's default report generator then you will need to download and install [Apache FOP](#). After extracting the FOP archive you will need to include the directory you extracted to in your PATH.

Next...

Connecting to a database.

Troubleshooting

1. any error related to lxml.

In order to be able to compile lxml, you have to install a C compiler (on GNU/Linux this would be the `gcc` package) and Cython (a Python specialization, that gets compiled into C code. Note: Cython is not CPython).

However, It should not be necessary to compile anything, and `pip` should be able to locate the binary modules in the online libraries.

For some reason, this is not the case on Windows 8.1.

<https://pypi.python.org/pypi/lxml/3.4.4>

Please report any other trouble related to the installation of lxml.

2. Couldn't install gdata.

For some reason the Google's gdata package lists itself in the Python Package Index but doesn't work properly with the `easy_install` command. You can download the latest gdata package from:

<http://code.google.com/p/gdata-python-client/downloads/list>

Unzip it and run `python setup.py installw` in the folder you unzip it to.

Next...

Connecting to a database.

Initial Configuration

After a successful installation, more complex organizations will need configure their database, and configure Ghini according to their database configuration. This page focuses on this task. If you don't know what this is about, please do read the part relative to SQLite.

Should you SQLite?

Is this the first time you use Ghini, are you going to work in a stand-alone setting, you have not the faintest idea how to manage a database management system? If you answered yes to any of the previous, you probably better stick with SQLite, the easy, fast, zero-administration file-based database.

With SQLite, you do not need any preparation and you can continue with *connecting*.

On the other hand, if you want to connect more than one bauble workstation to the same database, or if you want to make your data available for other clients, as could be a web server in a LAMP setting, you should consider keeping your database in a database management system like PostgreSQL or MySQL/MariaDB, both supported by Ghini.

When connecting to a database server as one of the above, you have to manually create: at least one bauble user, the database you want bauble to use, and to give at least one bauble user full permissions on its database. When this is done, Ghini will be able to proceed, creating the tables and importing the default data set. The process is database-dependent and it falls beyond the scope of this manual.

If you already got the chills or sick at your stomach, no need to worry, just stick with SQLite, you do not miss on features nor performance.

Connecting to a database

When you start Ghini the first thing that comes up is the connection dialog.

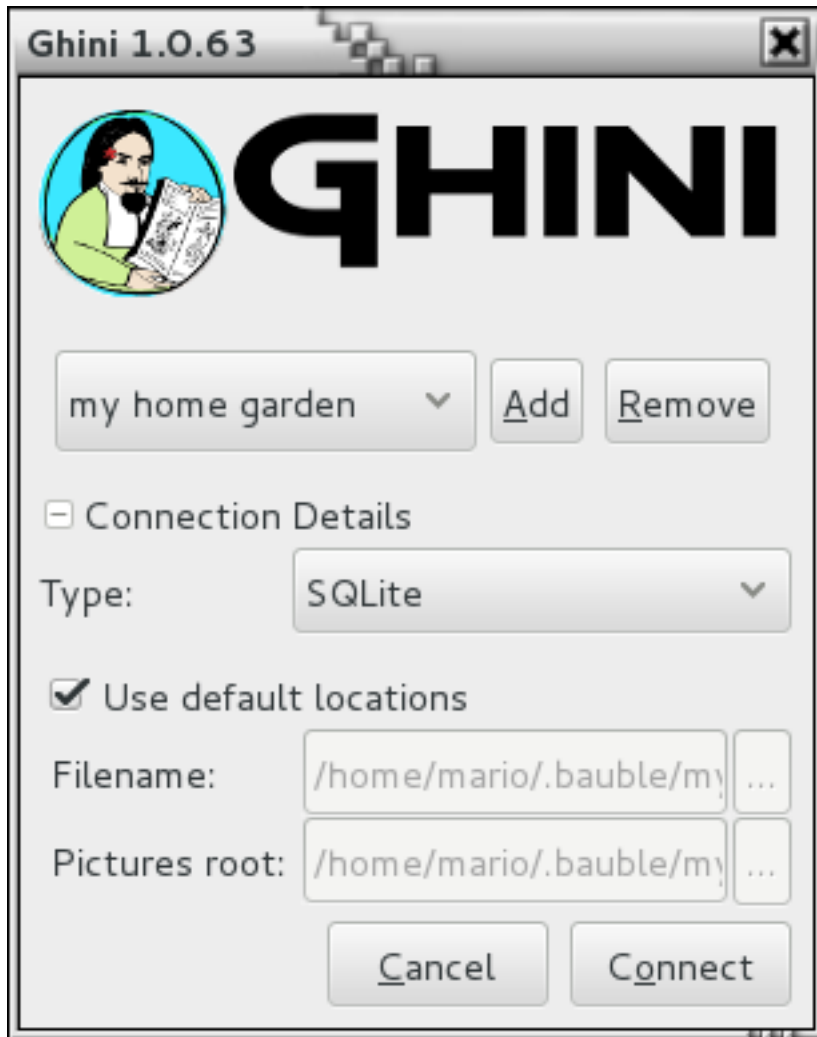

Quite obviously, if this is the first time you start Ghini, you have no connections yet and Ghini will alert you about it.

This alert will show at first activation and also in the future if your connections list becomes empty. As it says: click on **Add** to create your first connection.

Just insert a name for your connection, something meaningful you associate with the collection to be represented in the database (for example: “my home garden”), and click on **OK**. You will be back to the previous screen, but your connection name will be selected and the Connection Details will have expanded.

specify the connection details

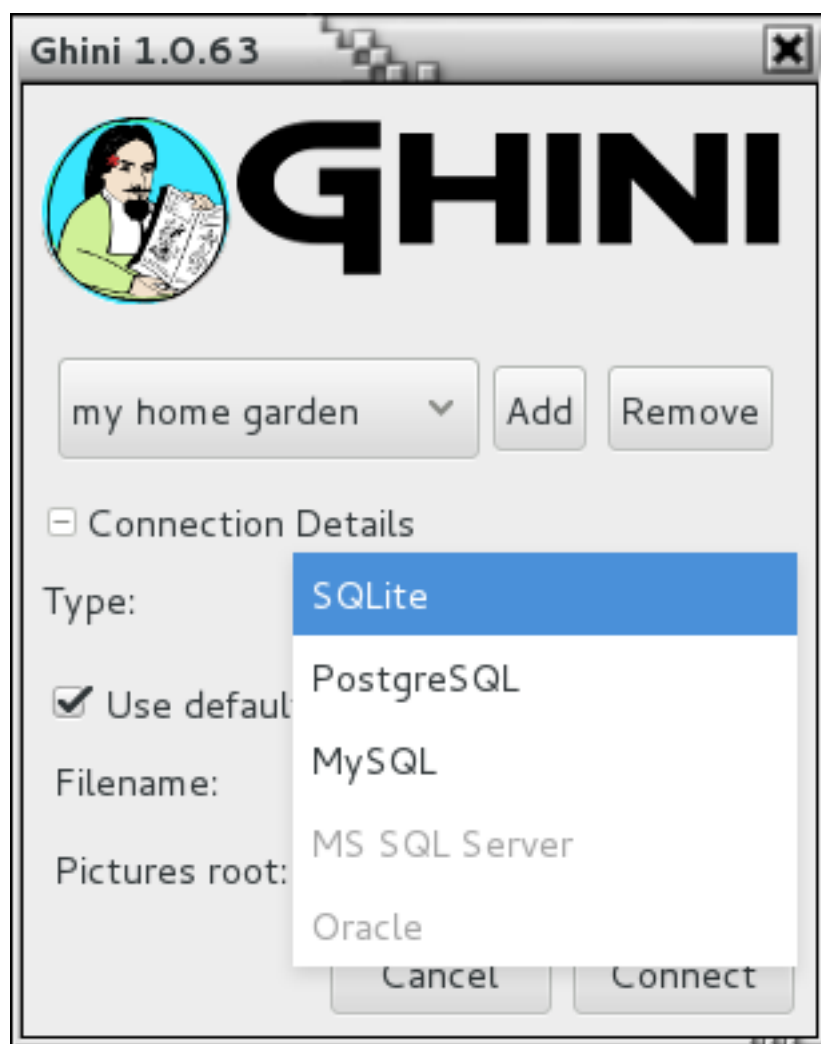

If you do not know what to do here, Ghini will help you stay safe. Activate the **Use default locations** check box and create your first connection by clicking on **Connect**.

You may safely skip the remainder of this section for the time being and continue reading to the following section.

fine-tune the connection details

By default Ghini uses the file-based SQLite database. During the installation process you had the choice (and you still have after installation), to add database connectors other than the default SQLite.

In this example, Ghini can connect to SQLite, PostgreSQL and MySQL, but no connector is available for Oracle or MS SQL Server.

If you use SQLite, all you really need specify is the connection name. If you let Ghini use the default filename then Ghini creates a database file with the same name as the connection and .db extension, and a pictures folder with the same name and no extension, both in `~/.bauble` on Linux/MacOSX or in `AppData\Roaming\Bauble` on Windows.

Still with SQLite, you might have received or downloaded a bauble database, and you want to connect to it. In this case you do not let Ghini use the default filename, but you browse in your computer to the location where you saved the Ghini SQLite database file.

If you use a different database connector, the dialog box will look different and it will offer you the option to fine tune all parameters needed to connect to the database of your choice.

If you are connecting to an existing database you can continue to [Editing and Inserting Data](#) and subsequently [Searching in Ghini](#), otherwise read on to the following section on initializing a database for Ghini.

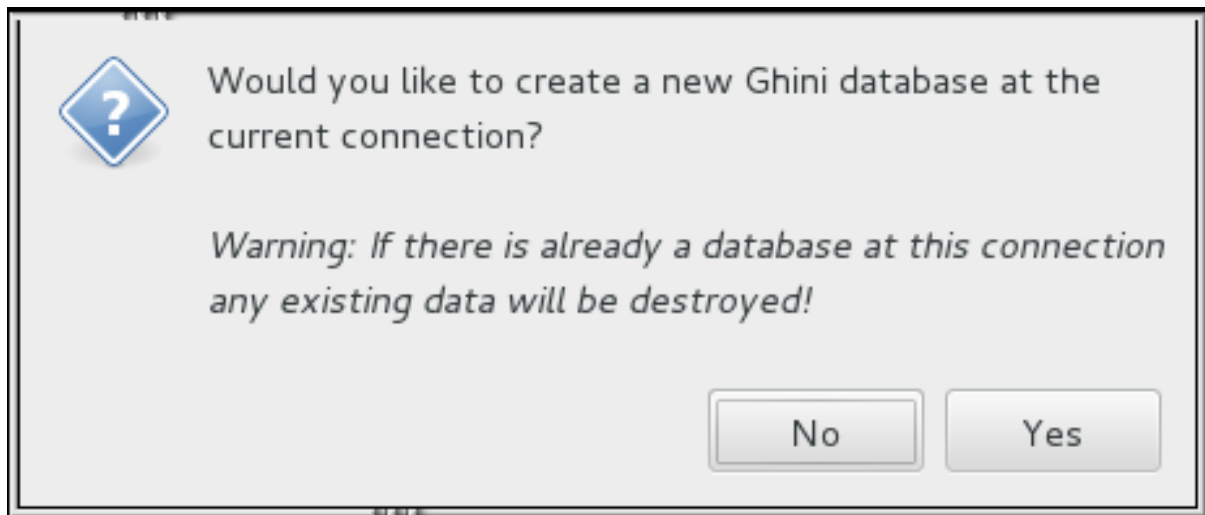

If you plan to associate pictures to plants, specify also the *pictures root* folder. The meaning of this is explained in further detail at [Pictures](#) in [Editing and Inserting Data](#).

Initialize a database

First time you open a connection to a database which had never been seen by Ghini before, Ghini will first display an alert:

immediately followed by a question:

Be careful when manually specifying the connection parameters: the values you have entered may refer to an existing database, not intended for use with Ghini. By letting Ghini initialize a database, the database will be emptied and all of its content be lost.

If you are sure you want to create a database at this connection then select "Yes". Ghini will then start creating the database tables and importing the default data. This can take a minute or two so while all of the default data is imported into the database so be patient.

Once your database has been created, configured, initialized, you are ready to start [Editing and Inserting Data](#) and subsequently [Searching in Ghini](#).

Searching in Ghini

Searching allows you to view, browse and create reports from your data. You can perform searches by either entering the queries in the main search entry or by using the Query Builder

to create the queries for you. The results of Ghini searches are listed in the main window.

Search Strategies

Ghini offers four distinct search strategies:

- by value — in all domains;
- by expression — in a few implicit fields in one explicit domain;
- by query — in one domain;
- by binomial name — only searches the Species domain.

All search strategies —with the notable exception of the binomial name search— are case insensitive.

Search by Value

Search by value is the simplest way to search. You enter one or more strings and see what matches. The result includes objects of any type (domain) where one or more of its fields contain one or more of the search strings.

You don't specify the search domain, all are included, nor do you indicate which fields you want to match, this is implicit in the search domain.

The following table helps you understand the results and guides you in formulating your searches.

search domain overview		
name and shorthands	field	result type
family, fam	epithet (family)	Family
genus, gen	epithet (genus)	Genus
species, sp	epithet (sp) ×	Species
vernacular, common, vern	name	Species
geography, geo	name	Geography
accession, acc	code	Accession
planting, plant	code ×	Plant
location, loc	code, name	Location
contact, person, org, source	name	Contact
collection, col, coll	locale	Collection
tag, tags	name	Tag

Examples of searching by value would be: Maxillaria, Acanth, 2008.1234, 2003.2.1, indica.

Unless explicitly quoted, spaces separate search strings. For example if you search for `Block 10` then Ghini will search for the strings `Block` and `10` and return all the results that match either of these strings. If you want to search for `Block 10` as one whole string then you should quote the string like `"Block 10"`.

× Composite Primary Keys

A **species** epithet means little without the corresponding genus, likewise a **planting** code is unique only within the accession to which it belongs. In database theory terminology, epithet and code are not sufficient to form a **primary key** for respectively species and planting. These domains need a **composite** primary key.

Search by value lets you look for **plantings** by their complete planting code, which includes the accession code. Taken together, Accession code and Planting code do provide a **composite primary key** for plantings. For **species**, we have introduced the binomial search, described below.

Search by Expression

Searching with expression gives you a little more control over what you are searching for. You narrow the search down to a specific domain, the software defines which fields to search within the domain you specified.

An expression is built as <domain> <operator> <value>. For example the search: `gen=Maxillaria` would return all the genera that match the name Maxillaria. In this case the domain is `gen`, the operator is `=` and the value is `Maxillaria`.

The above search domain overview table tells you the names of the search domains, and, per search domain, which fields are searched.

The search string `loc like block%` would return all the Locations for which name or code start with “block”. In this case the domain is `loc` (a shorthand for `location`), the operator is `like` (this comes from SQL and allows for “fuzzy” searching), the value is `block%`, the implicitly matched fields are `name` and `code`. The percent sign is used as a wild card so if you search for `block%` then it searches for all values that start with `max`. If you search for `%10` it searches for all values that end in `10`. The string `%ck%10` would search for all value that contain `ck` and end in `10`.

When a query takes ages to complete

You give a query, it takes time to compute, the result contains unreasonably many entries. This happens when you intend to use a strategy, but your strings do not form a valid expression. In this case Ghini falls back to *search by value*. For example the search string `gen lik maxillaria` will search for the strings `gen`, `lik`, and `maxillaria`, returning all that match at least one of the three criteria.

Binomial search

You can also perform a search in the database if you know the species, just by placing a few initial letters of genus and species epithets in the search engine, correctly capitalized, i.e.: **Genus epithet** with one leading capital letter, **Species epithet** all lowercase.

This way you can perform the search `So ha`.

These would be the initials for *Solanum hayesii*, or *Solanum havanense*.

Binomial search comes to compensate the limited usefulness of the above search by expression when trying to look for a species.

It is the correct capitalization **Xxxx xxxx** that informs the software of your intention to perform a binomial search. The software's second guess will be a search by value, which will possibly result in far more matches than you had expected.

The similar request `so ha` will return, in a fresh install, over 3000 objects, starting at Family “Acalyp(**ha**)ceae”, ending at Geography “Western (**So**)uth America”.

Search by Query

Queries allow the most control over searching. With queries you can search across relations, specific columns, combine search criteria using boolean operators like `and`, `or`, `not` (and their shorthands `&`, `|`, `!`), enclose them in parentheses, and more.

Please contact the authors if you want more information, or if you volunteer to document this more thoroughly. In the meanwhile you may start familiarizing yourself with the core structure of Ghini's database.

Fig. 3.1: core structure of Ghini's database

A few examples:

- plantings of family Fabaceae in location Block 10:

```
plant WHERE accession.species.genus.family.epithet=Fabaceae AND ↵  
→location.description="Block 10"
```

- locations that contain no plants:

```
location WHERE plants = Empty
```

- accessions associated to a species of known binomial name (e.g.: *Mangifera indica*):

```
accession WHERE species.genus.epithet=Mangifera AND species.  
→epithet=indica
```

- accessions we propagated in the year 2016:

```
accession WHERE plants.propagations._created BETWEEN ↵  
→|datetime|2016,1,1| AND |datetime|2017,1,1|
```

- accessions we modified in the last three days:

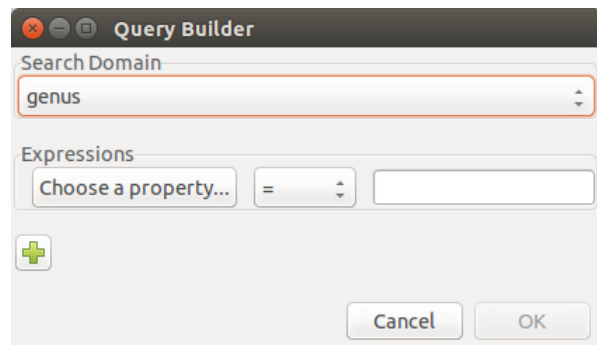

```
accession WHERE _last_updated>|datetime|-3|
```

Searching with queries requires some knowledge of a little syntax and an idea of the extensive Ghini database table structure. Both you acquire with practice, and with the help of the Query Builder.

The Query Builder

Ghini offers a Query Builder, that helps you build complex search queries through a point and click interface. To open the Query Builder click the  icon to the left of the search entry or select *Tools*→*Query Builder* from the menu.

A window will show up, which will lead you through all steps necessary to construct a correct query that is understood by Ghini's Query Search Strategy.

First of all you indicate the search domain, this will allow the Query Builder complete its graphical user interface, then you add as many logical clauses as you need, connecting them with a and or or binary operator.

Each clause is formed of three parts: a property that can be reached from the starting search domain, a comparison operator that you select from the drop-down list, a value that you can either type or select from the list of valid values for the field.

Add as many search properties as you need, by clicking on the plus sign. Select and/or next to the property name to choose how the clauses will be combined in the search query.

When you are done building your query click OK to perform the search.

Query Grammar

For those who don't fear a bit of formal precision, the following BNF code gives you a rather precise idea of the grammar implemented by the Query Search Strategy. Some grammatical categories are informally defined; any missing ones are left to your fertile imagination; literals are included in single quotes; the grammar is mostly case insensitive, unless otherwise stated:

```
query ::= domain 'WHERE' expression
domain ::= #( one of our search domains )
```

```
expression ::= signed_clause
            | signed_clause 'AND' expression
            | signed_clause 'OR' expression
            ;
signed_clause ::= clause
              | 'NOT' clause   #( not available in Query Builder)
              ;
clause ::= field_name binop value   #( available in Query Builder)
        | field_name set_binop value_list
        | aggregated binop value
        | field_name 'BETWEEN' value 'AND' value
        | '(' expression ')'
        ;
field_name ::=  #( path to reach a database field or connected table,
             ↪)
aggregated ::= aggregating_func '(' field_name ')'
aggregating_func ::= 'SUM'
                  | 'MIN'
                  | 'MAX'
                  | 'COUNT'
                  ;
value ::= typed_value
       | numeric_value
       | none_token
       | empty_token
       | string_value
       ;
typed_value ::= '|' type_name '|' value_list '|'
numeric_value ::=  #( just a number )
none_token ::= 'None'       #( case sensitive )
empty_token ::= 'Empty'     #( case sensitive )
string_value = quoted_string | unquoted_string

type_name ::= 'datetime' | 'bool' ;  #( only ones for the time,
             ↪being )
quoted_string ::= '"' unquoted_string '"'
unquoted_string ::=  #( alphanumeric and more )

value_list ::= value ',' value_list
            | value
            ;
binop ::= '='
        | '=='
        | '!='
        | '<>'
        | '<'
        | '<='
        | '>'
        | '>='
        | 'LIKE'
```

```

        | 'CONTAINS'
    ;
set_binop ::= 'IN'

```

Please be aware that Ghini's Query language is quite a bit more complex than what the Query Builder can produce: Queries you can build with the Query Builder form a proper subset of the queries recognized by the software:

```

query ::= domain 'WHERE' expression

domain ::= #( one of our search domains )
expression ::= clause
               | clause 'AND' expression
               | clause 'OR' expression
               ;
clause ::= field_name binop value
         ;
field_name ::= #( path to reach a database field or connected table_
→)
value ::= numeric_value
         | string_value
         ;
numeric_value ::= #( just a number )
string_value = quoted_string | unquoted_string ;

quoted_string ::= '"' unquoted_string '"'
unquoted_string ::= #( alphanumeric and more )

binop ::= '='
        | '=='
        | '!='
        | '<>'
        | '<'
        | '<='
        | '>'
        | '>='
        | 'LIKE'
        | 'CONTAINS'
        ;

```

Editing and Inserting Data

The main way that we add or change information in Ghini is by using the editors. Each basic type of data has its own editor. For example there is a Family editor, a Genus editor, an Accession editor, etc.

To create a new record click on the *Insert* menu on the menubar and then select the type of record you would like to create. This opens a new blank editor for the type.

To edit an existing record in the database right click on an item in the search results and select *Edit* from the popup menu. This opens an editor that allows you to change the values on the record that you selected.

Most types also have children which you can add by right clicking on the parent and selecting “Add ???...” on the context menu. For example, a Family has Genus children: you can add a Genus to a Family by right clicking on a Family and selecting “Add genus”.

Notes

Almost all of the editors in Ghini have a *Notes* tab which should work the same regardless of which editor you are using.

If you enter a web address in a note then the link shows up in the Links box when the item you are editing is selected in the search results.

You can browse the notes for an item in the database using the Notes box at the bottom of the screen. The Notes box is desensitized if the selected item does not have any notes.

Family

The Family editor allows you to add or change a botanical family.

The *Family* field on the editor lets you change the epithet of the family. The Family field is required.

The *Qualifier* field lets you change the family qualifier. The value can either be *sensu lato*, *sensu stricto*, or nothing.

Synonyms allow you to add other families that are synonyms with the family you are currently editing. To add a new synonym type in a family name in the entry. You must select a family name from the list of completions. Once you have selected a family name that you want to add as a synonym click on the Add button next to the synonym list and the software adds the selected synonym to the list. To remove a synonym, select the synonym from the list and click on the Remove button.

To cancel your changes without saving then click on the *Cancel* button.

To save the family you are working on then click *OK*.

To save the family you are working on and add a genus to it then click on the *Add Genera* button.

To add another family when you are finished editing the current one click on the *Next* button on the bottom. This saves the current family and opens a new blank family editor.

Genus

The Genus editor allows you to add or change a botanical genus.

The *Family* field on the genus editor allows you to choose the family for the genus. When you begin type a family name it will show a list of families to choose from. The family name must already exist in the database before you can set it as the family for the genus.

The *Genus* field allows you to set the genus for this entry.

The *Author* field allows you to set the name or abbreviation of the author(s) for the genus.

Synonyms allow you to add other genera that are synonyms with the genus you are currently editing. To add a new synonym type in a genus name in the entry. You must select a genus name from the list of completions. Once you have selected a genus name that you want to add as a synonym click on the Add button next to the synonym list and it will add the selected synonym to the list. To remove a synonym select the synonym from the list and click on the Remove button.

To cancel your changes without saving then click on the *Cancel* button.

To save the genus you are working on then click *OK*.

To save the genus you are working on and add a species to it then click on the *Add Species* button.

To add another genus when you are finished editing the current one click on the *Next* button on the bottom. This will save the current genus and open a new blank genus editor.

Species/Taxon

For historical reasons called a *species*, but by this we mean a *taxon* at rank *species* or lower. It represents a unique name in the database. The species editor allows you to construct the name as well as associate metadata with the taxon such as its distribution, synonyms and other information.

The *Infraspecific parts* in the species editor allows you to specify the *taxon* further than at *species* rank.

To cancel your changes without saving then click on the *Cancel* button.

To save the species you are working on then click *OK*.

To save the species you are working on and add an accession to it then click on the *Add Accession* button.

To add another species when you are finished editing the current one click on the *Next* button on the bottom. This will save the current species and open a new blank species editor.

Accessions

The Accession editor allows us to add an accession to a species. In Ghini an accession represents a group of plants or clones. The accession would refer maybe a group of seed or cuttings from a species. A plant would be an individual from that accesssion, i.e. a specific plant in a specific location.

Accession Source

The source of the accessions lets you add more information about where this accession came from. At the moment the type of the source can be either a Collection or a Donation.

Collection

A Collection.

Donation

A Donation.

Plant

The Plant editor.

Creating multiple plants

You can create multiple Plants by using ranges in the code entry. This is only allowed when creating new plants and it is not possible when editing existing Plants in the database.

For example the range, 3-5 will create plant with code 3,4,5. The range 1,4-7,25 will create plants with codes 1,4,5,6,7,25.

When you enter the range in the plant code entry the entry will turn blue to indicate that you are now creating multiple plants. Any fields that are set while in this mode will be copied to all the plants that are created.

Pictures

Just as almost all objects in the Ghini database can have *Notes* associated to them, Plants can have *Pictures*: next to the tab for Notes, the Plants editor contains an extra tab called “Pictures”. You can associate as many pictures as you might need to a plant.

When you associate a picture to a plant, the file is copied in the *pictures* folder, and a miniature (500x500) is generated and copied in the *thumbnails* folder inside of the pictures folder.

As of Ghini-1.0.62, Pictures are not kept in the database. To ensure pictures are available on all terminals where you have installed and configured Ghini, you can use a file sharing service like Copy or Dropbox. The personal choice of the writer of this document is to use Copy, because it offers much more space and because of its “Fair Storage” policy.

Remember that you have configured the pictures root folder when you specified the details of your database connection. Again, you should make sure that the pictures root folder is shared with your file sharing service of choice.

When a Plant in the current selection is highlighted, its pictures are displayed in the pictures pane, the pane left of the information pane. When an accession in the selection is highlighted, any picture associated to the plants in the highlighted accession are displayed in the pictures pane.

Locations

The Location editor

danger zone

The location editor contains an initially hidden section named *danger zone*. The widgets contained in this section allow the user to merge the current location into a different location, letting the user correct spelling mistakes or implement policy changes.

Dealing with Propagations

Ghini offers the possibility to associate Propagations trials to Plants and to document their treatments and results. Treatments are integral parts of the description of a Propagation trial. If a Propagation trial is successful, Ghini lets you associate it to a new Accession. You can only associate one Accession to a Propagation Trial.

Here we describe how you use this part of the interface.

Creating a Propagation

A Propagation (trial) is obtained from a Plant. Ghini reflects this in its interface: you select a plant, open the Plant Editor on it, activate the Propagation Tab, click on Add.

When you do the above, you get a Propagation Editor window. Ghini does not consider Propagation trials as independent entities. As a result, Ghini treats the Propagation Editor as a special editor window, which you can only reach from the Plant Editor.

For a new Propagation, you select the type of propagation (this becomes an immutable property of the propagation) then insert the data describing it.

You will be able to edit the propagation data via the same path: select a plant, open the Plant Editor, identify the propagation you want to edit, click on the corresponding Edit button. You will be able to edit all properties of an existing Propagation trial, except its type.

In the case of a seed propagation trial, you have a pollen parent, and a seed parent. You should always associate the Propagation trial to the seed parent.

Nota: In Ghini-1.0 you specify the pollen parent plant in the “Notes” field, while Ghini-1.1 has a (relation) field for it. According to ITF2, there might be cases in seed propagation trials where it is not known which Plant plays which role. Again, in Ghini-1.0 you should use a note

to indicate whether this is the case, Ghini-1.1 has a (boolean) field indicating whether this is the case.

Using a Propagation

A Propagation trial may be successful and result in a new Accession.

Ghini helps you reflect this in the database: create a new Accession, immediately switch to the Source tab and select “Garden Propagation” in the (admittedly somewhat misleading) Contact field.

Start typing the plant number and a list of matching plants with propagation trials will appear for you to select from.

Select the plant, and the list of accessed and unaccessed propagation trials will appear in the lower half of the window.

Select a still unaccessed propagation trial from the list and click on Ok to complete the operation.

Using the data from the Propagation trial, Ghini completes some of the fields in the General tab: Taxon name, Type of material, and possibly Provenance. You will be able to edit these fields, but please note that the software will not prevent introducing conceptual inconsistencies in your database.

You can associate a Propagation trial to only one Accession.

Tagging

Tagging is an easy way to give context to an object or create a collection of object that you want to recall later. For example if you want to collect a bunch of plants that you later want to create a report from you can tag them with the string “for that report i was thinking about”. You can then select “for that report i was thinking about” from the tags menu to show you all the objects you tagged.

Tagging can be done two ways. By selecting one or more items in the search results and pressing Ctrl-T or by selecting *Tag→Tag Selection* from the menu. If you have selected multiple items then only that tags that are common to all the selected items will have a check next to it.

Generating reports

A database without exporting facilities is of little use. Ghini lets you export your data in table format (open them in your spreadsheet editor of choice), as labels (to be printed or engraved), as html pages or pdf or postscript documents.

This page describes the two tools Ghini offers for these tasks.

Using the Mako Report Formatter

The Mako report formatter uses the Mako template language for generating reports. More information about Mako and its language can be found at makotemplates.org.

The Mako templating system should already be installed on your computer if Ghini is installed.

Creating reports with Mako is similar in the way that you would create a web page from a template. It is much simpler than the XSL Formatter(see below) and should be relatively easy to create template for anyone with a little but of programming experience.

The template generator will use the same file extension as the template which should indicate the type of output the template with create. For example, to generate an HTML page from your template you should name the template something like *report.html*. If the template will generate a comma seperated value file you should name the template *report.csv*.

The template will receive a variable called *values* which will contain the list of values in the current search.

The type of each value in *values* will be the same as the search domain used in the search query. For more information on search domains see search-domains.

If the query does not have a search domain then the values could all be of a different type and the Mako template should prepared to handle them.

Using the XSL Report Formatter

The XSL report formatter requires an XSL to PDF renderer to convert the data to a PDF file. Apache FOP is is a free and open-source XSL->PDF renderer and is recommended.

If using Linux, Apache FOP should be installable using your package manager. On Debian/Ubuntu it is installable as `fop` in Synaptic or using the following command:

```
apt-get install fop
```

Installing Apache FOP on Windows

You have two options for installing FOP on Windows. The easiest way is to download the prebuilt [ApacheFOP-0.95-1-setup.exe](#) installer.

Alternatively you can download the [archive](#). After extracting the archive you must add the directory you extracted the archive to to your PATH environment variable.

Importing and Exporting Data

Although Ghini can be extended through plugins to support alternate import and export formats, by default it can only import and export comma seperated values files or CSV.

There is some support for exporting to the Access for Biological Collections Data it is limited.

There is also limited support for exporting to an XML format that more or less reflects exactly the tables and row of the database.

Exporting ABCD and XML will not be covered here.

Avvertimento: Importing files will most likely destroy any data you have in the database so make sure you have backed up your data.

Importing from CSV

In general it is best to only import CSV files into Ghini that were previously exported from Ghini. It is possible to import any CSV file but that is more advanced than this doc will cover.

To import CSV files into Ghini select *Tools→Export→Comma Separated Values* from the menu.

After clicking OK on the dialog that asks if you are sure you know what you're doing a file chooser will open. In the file chooser select the files you want to import.

Exporting to CSV

To export the Ghini data to CSV select *Tools→Export→Comma Separated Values* from the menu.

This tool will ask you to select a directory to export the CSV data. All of the tables in Ghini will be exported to files in the format `tablename.txt` where `tablename` is the name of the table where the data was exported from.

Importing from JSON

This is *the* way to import data into an existing database, without destroying previous content. A typical example of this functionality would be importing your digital collection into a fresh, just initialized Ghini database. Converting a database into a JSON interchange format is beyond the scope of this manual, please contact one of the authors if you need any further help.

Using the Ghini JSON interchange format, you can import data which you have exported from a different Ghini installation.

Exporting to JSON

This feature is still under development.

when you activate this export tool, you are given the choice to specify what to export. You can use the current selection to limit the span of the export, or you can start at the complete content of a domain, to be chosen among Species, Accession, Plant.

Exporting *Species* will only export the complete taxonomic information in your database. *Accession* will export all your accessions plus all the taxonomic information it refers to: unreferred to taxa will not be exported. *Plant* will export all living plants (some accession might not be included), all referred to locations and taxa.

Managing Users

Nota: The Ghini users plugin is only available on PostgreSQL based databases.

The Ghini User's Plugin will allow you to create and manage the permissions of users for your Ghini database.

Creating Users

To create a new user...

Permissions

Ghini allows read, write and execute permissions.

Database Administration

Nel caso si stia utilizzando un vero e proprio DBMS (sistema di gestione di basi di dati) per contenere le collezioni di Bauble, è importante prendere in considerazione l'amministrazione di questo DBMS. Una descrizione del compito di amministrare una base dati è qui assolutamente fuori luogo, ma è importante che un utente sia consapevole del problema.

SQLite

SQLite offre una soluzione in quanto SQLite non è esattamente quanto si potrebbe definire un DMBS: ogni base dati SQLite è un file, farne copia di emergenza (backup) sarà sufficiente. Se si è creata la connessione alla base dati SQLite accettando i valori per difetto, il file relativo alla connessione si trova nella directory `~/.bauble/` (con Windows bisognerà trovare la AppData).

In Windows it is somewhere in your AppData directory, most likely in `AppData\Roaming\Bauble`. Do keep in mind that Windows does its best to hide the AppData directory structure to normal users.

The fastest way to open it is with the file explorer: type `“%APPDATA%”` and hit enter.

MySQL

Prego riferirsi alla documentazione ufficiale.

PostgreSQL

Prego riferirsi alla documentazione ufficiale. Una discussione molto approfondita sulle varie opzioni di backup inizia al [chapter_24](#).

Ghini Configuration

Ghini uses a configuration file to store values across invocations. This file is associated to a user account and every user will have their own configuration file.

To review the content of the Ghini configuration file, type `:prefs` in the text entry area where you normally type your searches, then hit enter.

You normally do not need tweaking the configuration file, but you can do so with a normal text editor program. Ghini configuration file is at the default location for SQLite databases.

Reporting Errors

Should you notice anything unexpected in Ghini's behaviour, please consider filing an issue on the Ghini development site.

Ghini development site can be accessed via the Help menu.

Developer's Manual

Helping Ghini development

Installing Ghini always includes downloading the sources, connected to the github repository. This is so because in our eyes, every user is always potentially also a developer.

If you want to contribute to Ghini, you can do so in quite a few different ways:

- Use the software, note the things you don't like, [open an issue](#) for each of them. A developer will react sooner than you can imagine.
- If you have an idea of what you miss in the software but can't quite formalize it into separate issues, you could consider hiring a professional. This is the best way to make sure that something happens quickly on Ghini. Do make sure the developer opens issues and publishes their contribution on github.
- Translate! Any help with translations will be welcome, so please do! you can do this without installing anything on your computer, just using the on-line translation service offered by <http://hosted.weblate.org/>
- fork the repository, choose an issue, solve it, open a pull request. See the [bug solving workflow](#) below.

If you haven't yet installed Ghini, and want to have a look at its code history, you can open our [github project page](#) and see all that has been going on around Ghini since its inception as Bauble, back in the year 2004.

Software source, versions, branches

If you want a particular version of Ghini, we release and maintain versions as branches. You should `git checkout` the branch corresponding to the version of your choice.

production line

Branch names for Ghini stable (production) versions are of the form `ghini-x.y` (eg: `ghini-1.0`); branch names where Ghini testing versions are published are of the form `ghini-x.y-dev` (eg: `ghini-1.0-dev`).

Development Workflow

Our workflow is to continuously commit to the testing branch, to often push them to github, to let travis-ci and coveralls.io check the quality of the pushed testing branches, finally, from time to time, to merge the testing branch into the corresponding release.

When working at larger issues, which seem to take longer than a couple of days, I might open a branch associated to the issue. I don't do this very often.

larger issues

When facing a single larger issue, create a branch tag at the tip of a main development line (e.g.: `ghini-1.0-dev`), and follow the workflow described at

<https://git-scm.com/book/en/v2/Git-Branching-Basic-Branching-and-Merging>

in short:

```
git up
git checkout -b issue-xxxx
git push origin issue-xxxx
```

Work on the new temporary branch. When ready, go to github, merge the branch with the main development line from which you branched, solve conflicts where necessary, delete the temporary branch.

When ready for publication, merge the development line into the corresponding production line.

Updating the set of translatable strings

From time to time, during the process of updating the software, you will be adding or modifying strings in the python sources, in the documentation, in the glade sources. Most of our strings are translatable, and are offered to weblate for people to contribute, in the form of several `.po` files. These `po` files receive contributions from weblate, and offer lines without translation from new lines of code.

We have organized the translation of ghini as two separate repositories in github, each repository being associated to sections of the same project on weblate. Translation of the software is in ghini.desktop, the software project, while translation of the documentation —itself part of the software— is in a separate project, ghini.desktop-docs.i18n.

To update the po files relative to the software, you run a script from the project root dir:

```
./scripts/i18n.sh
```

This will update your po files, something you need commit and push to github.

We haven't yet defined a workflow for publishing translated documentation on readthedocs. If you have experience with it please have a go at it. Thank you in advance.

Adding missing unit tests

If you are interested contributing to development of Ghini, a good way to do so would be by helping us finding and writing the missing unit tests.

A well tested function is one whose behaviour you cannot change without breaking at least one unit test.

We all agree that in theory theory and practice match perfectly and that one first writes the tests, then implements the function. In practice, however, practice does not match theory and we have been writing tests after writing and even publishing the functions.

This section describes the process of adding unit tests for `bauble.plugins.plants.family.remove_callback`.

What to test

First of all, open the coverage report index, and choose a file with low coverage.

For this example, run in October 2015, we landed on `bauble.plugins.plants.family`, at 33%.

<https://coveralls.io/builds/3741152/source?filename=bauble%2Fplugins%2Fplants%2Ffamily.py>

The first two functions which need tests, `edit_callback` and `add_genera_callback`, include creation and activation of an object relying on a custom dialog box. We should really first write unit tests for that class, then come back here.

The next function, `remove_callback`, also activates a couple of dialog and message boxes, but in the form of invoking a function requesting user input via yes-no-ok boxes. These functions we can easily replace with a function mocking the behaviour.

how to test

So, having decided what to describe in unit test, we look at the code and we see it needs discriminate a couple of cases:

parameter correctness

- the list of families has no elements.
- the list of families has more than one element.
- the list of families has exactly one element.

cascade

- the family has no genera
- the family has one or more genera

confirm

- the user confirms deletion
- the user does not confirm deletion

deleting

- all goes well when deleting the family
- there is some error while deleting the family

I decide I will only focus on the **cascade** and the **confirm** aspects. Two binary questions: 4 cases.

where to put the tests

Locate the test script and choose the class where to put the extra unit tests.

<https://coveralls.io/builds/3741152/source?filename=bauble%2Fplugins%2Fplants%2Ftest.py#L273>

Nota: The `FamilyTests` class contains a skipped test, implementing it will be quite a bit of work because we need rewrite the `FamilyEditorPresenter`, separate it from the `FamilyEditorView` and reconsider what to do with the `FamilyEditor` class, which I think should be removed and replaced with a single function.

writing the tests

After the last test in the `FamilyTests` class, I add the four cases I want to describe, and I make sure they fail, and since I'm lazy, I write the most compact code I know for generating an error:

```
def test_remove_callback_no_genera_no_confirm(self):
    1/0

def test_remove_callback_no_genera_confirm(self):
    1/0

def test_remove_callback_with_genera_no_confirm(self):
```

```
1/0

def test_remove_callback_with_genera_confirm(self):
    1/0
```

One test, step by step

Let's start with the first test case.

When writing tests, I generally follow the pattern:

- T_0 (initial condition),
- action,
- T_1 (testing the result of the action given the initial conditions)

Nota: There's a reason why unit tests are called unit tests. Please never test two actions in one test.

So let's describe T_0 for the first test, a database holding a family without genera:

```
def test_remove_callback_no_genera_no_confirm(self):
    f5 = Family(family=u'Arecaceae')
    self.session.add(f5)
    self.session.flush()
```

We do not want the function being tested to invoke the interactive `utils.yes_no_dialog` function, we want `remove_callback` to invoke a non-interactive replacement function. We achieve this simply by making `utils.yes_no_dialog` point to a lambda expression which, like the original interactive function, accepts one parameter and returns a boolean. In this case: `False`:

```
def test_remove_callback_no_genera_no_confirm(self):
    # T_0
    f5 = Family(family=u'Arecaceae')
    self.session.add(f5)
    self.session.flush()

    # action
    utils.yes_no_dialog = lambda x: False
    from bauble.plugins.plants.family import remove_callback
    remove_callback(f5)
```

Next we test the result.

Well, we don't just want to test whether or not the object `Arecaceae` was deleted, we also should test the value returned by `remove_callback`, and whether `yes_no_dialog` and `message_details_dialog` were invoked or not.

A lambda expression is not enough for this. We do something apparently more complex, which will make life a lot easier.

Let's first define a rather generic function:

```
def mockfunc(msg=None, name=None, caller=None, result=None):
    caller.invoked.append((name, msg))
    return result
```

and we grab `partial` from the `functools` standard module, to partially apply the above `mockfunc`, leaving only `msg` unspecified, and use this partial application, which is a function accepting one parameter and returning a value, to replace the two functions in `utils`. The test function now looks like this:

```
def test_remove_callback_no_genera_no_confirm(self):
    # T_0
    f5 = Family(family=u'Arecaceae')
    self.session.add(f5)
    self.session.flush()
    self.invoked = []

    # action
    utils.yes_no_dialog = partial(
        mockfunc, name='yes_no_dialog', caller=self, result=False)
    utils.message_details_dialog = partial(
        mockfunc, name='message_details_dialog', caller=self)
    from bauble.plugins.plants.family import remove_callback
    result = remove_callback([f5])
    self.session.flush()
```

The test section checks that `message_details_dialog` was not invoked, that `yes_no_dialog` was invoked, with the correct message parameter, that `Arecaceae` is still there:

```
# effect
self.assertFalse('message_details_dialog' in
                 [f for (f, m) in self.invoked])
self.assertTrue(('yes_no_dialog', u'Are you sure you want to '
                 'remove the family <i>Arecaceae</i>?')
                in self.invoked)
self.assertEqual(result, None)
q = self.session.query(Family).filter_by(family=u"Arecaceae")
matching = q.all()
self.assertEqual(matching, [f5])
```

And so on

there are two kinds of people, those who complete what they start, and so on

Next test is almost the same, with the difference that the `utils.yes_no_dialog` should return `True` (this we achieve by specifying `result=True` in the partial application of the generic mockfunc).

With this action, the value returned by `remove_callback` should be `True`, and there should be no `Arecaceae` Family in the database any more:

```
def test_remove_callback_no_genera_confirm(self):
    # T_0
    f5 = Family(family=u'Arecaceae')
    self.session.add(f5)
    self.session.flush()
    self.invoked = []

    # action
    utils.yes_no_dialog = partial(
        mockfunc, name='yes_no_dialog', caller=self, result=True)
    utils.message_details_dialog = partial(
        mockfunc, name='message_details_dialog', caller=self)
    from bauble.plugins.plants.family import remove_callback
    result = remove_callback([f5])
    self.session.flush()

    # effect
    self.assertFalse('message_details_dialog' in
                     [f for (f, m) in self.invoked])
    self.assertTrue(('yes_no_dialog', u'Are you sure you want to '
                        'remove the family <i>Arecaceae</i>?')
                    in self.invoked)
    self.assertEqual(result, True)
    q = self.session.query(Family).filter_by(family=u"Arecaceae")
    matching = q.all()
    self.assertEqual(matching, [])
```

have a look at commit `734f5bb9feffc2f4bd22578fcee1802c8682ca83` for the other two test functions.

Testing logging

Our `bauble.test.BaubleTestCase` objects use handlers of the class `bauble.test.MockLoggingHandler`. Every time an individual unit test is started, the `setUp` method will create a new handler and associate it to the root logger. The `tearDown` method takes care of removing it.

You can check for presence of specific logging messages in `self.handler.messages`. `messages` is a dictionary, initially empty, with two levels of indexation. First the name of the logger issuing the logging record, then the name of the level of the logging record. Keys are created when needed. Values hold lists of messages, formatted according to whatever formatter you associate to the handler, defaulting to `logging.Formatter("%(message)s")`.

You can explicitly empty the collected messages by invoking `self.handler.clear()`.

Putting all together

From time to time you want to activate the test class you're working at:

```
nosetests bauble/plugins/plants/test.py:FamilyTests
```

And at the end of the process you want to update the statistics:

```
./scripts/update-coverage.sh
```

Structure of user interface

The user interface is built according to the **Model — View — Presenter** architectural pattern. For much of the interface, **Model** is a SQLAlchemy database object, but we also have interface elements where there is no corresponding database model. In general:

- The **View** is described as part of a **glade** file. This should include the signal-callback and ListStore-TreeView associations. Just reuse the base class `GenericEditorView` defined in `bauble.editor`. When you create your instance of this generic class, pass it the **glade** file name and the root widget name, then hand this instance over to the **presenter** constructor.

In the glade file, in the `action-widgets` section closing your `GtkDialog` object description, make sure every `action-widget` element has a valid response value. Use valid `GtkResponseType` values, for example:

- `GTK_RESPONSE_OK`, -5
- `GTK_RESPONSE_CANCEL`, -6
- `GTK_RESPONSE_YES`, -8
- `GTK_RESPONSE_NO`, -9

There is no easy way to unit test a subclassed view, so please don't subclass views, there's really no need to.

In the glade file, every input widget should define which handler is activated on which signal. The generic Presenter class offers generic callbacks which cover the most common cases.

- `GtkEntry` (one-line text entry) will handle the `changed` signal, with either `on_text_entry_changed` or `on_unique_text_entry_changed`.
- `GtkTextView`: associate it to a `GtkTextBuffer`. To handle the `changed` signal on the `GtkTextBuffer`, we have to define a handler which invokes the generic `on_textbuffer_changed`, the only role for this function is to pass our generic handler the name of the model attribute that receives the change. This is a workaround for an [unresolved bug in GTK](#).
- `GtkComboBox` with translated texts can't be easily handled from the glade file, so we don't even try. Use the `init_translatable_combo` method of the generic `GenericEditorView` class, but please invoke it from the **presenter**.

- The **Model** is just an object with known attributes. In this interaction, the **model** is just a passive data container, it does nothing more than to let the **presenter** modify it.
- The subclassed **Presenter** defines and implements:
 - `widget_to_field_map`, a dictionary associating widget names to name of model attributes,
 - `view_accept_buttons`, the list of widget names which, if activated by the user, mean that the view should be closed,
 - all needed callbacks,
 - optionally, it plays the **model** role, too.

The **presenter** continuously updates the **model** according to changes in the **view**. If the **model** corresponds to a database object, the **presenter** commits all **model** updates to the database when the **view** is closed successfully, or rolls them back if the **view** is canceled. (this behaviour is influenced by the parameter `do_commit`)

If the **model** is something else, then the **presenter** will do something else.

Nota: A well behaved **presenter** uses the **view** api to query the values inserted by the user or to forcibly set widget statuses. Please do not learn from the practice of our misbehaving presenters, some of which directly handle fields of `view.widgets`. By doing so, these presenters prevents us from writing unit tests.

The base class for the presenter, `GenericEditorPresenter` defined in `bauble.editor`, implements many useful generic callbacks. There is a `MockView` class, that you can use when writing tests for your presenters.

Examples

`Contact` and `ContactPresenter` are implemented following the above lines. The view is defined in the `contact.glade` file.

A good example of Presenter/View pattern (no model) is given by the connection manager.

We use the same architectural pattern for non-database interaction, by setting the presenter also as model. We do this, for example, for the JSON export dialog box. The following command will give you a list of `GenericEditorView` instantiations:

```
grep -nHr -e GenericEditorView\ ( bauble
```

Extending Ghini with Plugins

Nearly everything about Ghini is extensible through plugins. Plugins can create tables, define custom searches, add menu items, create custom commands and more.

To create a new plugin you must extend the `bauble.pluginmgr.Plugin` class.

The `Tag` plugin is a good minimal example, even if the `TagItemGUI` falls outside the Model-View-Presenter architectural pattern.

Plugins structure

Ghini is a framework for handling collections, and is distributed along with a set of plugins making Ghini a botanical collection manager. But Ghini stays a framework and you could in theory remove all plugins we distribute and write your own, or write your own plugins that extend or complete the current Ghini behaviour.

Once you have selected and opened a database connection, you land in the Search window. The Search window is an interaction between two objects: `SearchPresenter` (SP) and `SearchView` (SV).

SV is what you see, SP holds the program status and handles the requests you express through SV. Handling these requests affect the content of SV and the program status in SP.

The search results shown in the largest part of SV are rows, objects that are instances of classes registered in a plugin.

Each of these classes must implement an amount of functions in order to properly behave within the Ghini framework. The Ghini framework reserves space to pluggable classes.

SP knows of all registered (plugged in) classes, they are stored in a dictionary, associating a class to its plugin implementation. SV has a slot (a `gtk.Box`) where you can add elements. At any time, at most only one element in the slot is visible.

A plugin defines one or more plugin classes. A plugin class plays the role of a partial presenter (pP - plugin presenter) as it implement the callbacks needed by the associated partial view fitting in the slot (pV - plugin view), and the MVP pattern is completed by the parent presenter (SP), again acting as model. To summarize and complete:

- SP acts as model,
- the pV partial view is defined in a glade file.
- the callbacks implemented by pP are referenced by the glade file.
- a context menu for the SP row,
- a children property.

when you register a plugin class, the SP:

- adds the pV in the slot and makes it non-visible.
- adds an instance of pP in the registered plugin classes.
- tells the pP that the SP is the model.
- connects all callbacks from pV to pP.

when an element in pV triggers an action in pP, the pP can forward the action to SP and can request SP that it updates the model and refreshes the view.

When the user selects a row in SP, SP hides everything in the pluggable slot and shows only the single pV relative to the type of the selected row, and asks the pP to refresh the pV with whatever is relative to the selected row.

Apart from setting the visibility of the various pV, nothing needs be disabled nor removed: an invisible pV cannot trigger events!

bug solving workflow

normal development workflow

- while using the software, you notice a problem, or you get an idea of something that could be better, you think about it good enough in order to have a very clear idea of what it really is, that you noticed. you open an issue and describe the problem. someone might react with hints.
- you open the issues site and choose one you want to tackle.
- assign the issue to yourself, this way you are informing the world that you have the intention to work at it. someone might react with hints.
- optionally fork the repository in your account and preferably create a branch, clearly associated to the issue.
- write unit tests and commit them to your branch (please do not push failing unit tests to github, run `nosetests` locally first).
- write more unit tests (ideally, the tests form the complete description of the feature you are adding or correcting).
- make sure the feature you are adding or correcting is really completely described by the unit tests you wrote.
- make sure your unit tests are atomic, that is, that you test variations on changes along one single variable. do not give complex input to unit tests or tests that do not fit on one screen (25 lines of code).
- write the code that makes your tests succeed.
- update the `i18n` files (run `./scripts/i18n.sh`).
- whenever possible, translate the new strings you put in code or glade files.
- commit your changes.
- push to github.
- open a pull request.

publishing to production

- open the pull request page using as base a production line `ghini-x.y`, compared to `ghini-x.y-dev`.

- make sure a bump commit is included in the differences.
- it should be possible to automatically merge the branches.
- create the new pull request, call it as “publish to the production line”.
- you possibly need wait for travis-ci to perform the checks.
- merge the changes.
- tell the world about it: on facebook, the google group, linkedin, ...

closing step

- review this workflow. consider this as a guideline, to yourself and to your colleagues. please help make it better and matching the practice.

CAPITOLO 6

Appoggiare Ghini

Se utilizzi Ghini, o se ti sembra giusto aiutarne lo sviluppo, puoi considerare una [donazione](#)
